Three rhizosphere soil samples from different vegetation types, including desertified slope, hilly area and hilly area after afforestation, were collected in this paper. The soil samples were collected in September 2009. The above three soils were chosen as the test soils, and the single-factor experiment was applied to explore the effects of added soluble salt (sodium nitrate) on soil primary active carbon (PAC) and soil microbial biomass phosphorus (SMBP). The results showed that, comparing to NaNO₃-0, the values of added soluble salt decreased both in PAC and SMBP of the three soil samples, and the rates were dependent on soil origin, soil pH and added salt concentration. With the increase of soil pH, the rates of changes of added salt decreased. The longer salinity had been added, the smaller effects on soil primary active carbon and soil microbial biomass phosphorus. The soil primary active carbon presented a higher response (82%-94%) to salt, but the soil microbial biomass phosphorus presented a lower response (68%-71%), comparing to soil organic matter.. Both the IPs and the VRFs associated with the VMM 300 can receive traffic packets from, or transmit traffic packets to, the VMs 300-306 through the port adapters 316-322. The VMkernel 300 operates to properly pass the traffic packets between the various VMs 300-306, each of which may be represented by its own IP address and IP:MAC address pair. This decoupling of the IP and MAC address in the VMM 300 is sometimes referred to as MAC or link virtualization. The functions performed by the VMM 300 are described with reference to FIG. 3. The VMkernel 300 includes a number of components, which will now be discussed. As noted above, the VMkernel includes the components of the IP layer (Internet layer), the transport layer (transport layer) and f678ea9f9e
